

Build a Personal Information Program

Complete Project Report

A beginner-friendly Python console application that collects basic user information and displays it as a formatted profile.

1. Description

Create a Python program that accepts a user's basic information and displays it in a clean formatted profile.

2. Objective

Learn and demonstrate variables, input(), type conversion, and formatted output using f-strings.

3. Tools

Python 3; VS Code / PyCharm / Jupyter Notebook.

4. Inputs

Name, age, email, phone number, city, and course. The age input is converted to an integer.

5. Output

A clean personal profile showing all entered details.

6. Methodology

The program declares meaningful variables, accepts values through input(), converts age using int(), and prints the stored values using f-strings.

7. Source Code

```
# Build a Personal Information Program
# Language: Python 3

print("=== Personal Information Profile ===")

name = input("Enter your name: ")
age = int(input("Enter your age: "))
email = input("Enter your email: ")
phone = input("Enter your phone number: ")
city = input("Enter your city: ")
course = input("Enter your course: ")

print("\n--- Personal Profile ---")
print(f"Name    : {name}")
print(f"Age     : {age}")
print(f"Email    : {email}")
print(f"Phone    : {phone}")
print(f"City     : {city}")
print(f"Course   : {course}")
print("-----")
```

8. Sample Output

```
=== Personal Information Profile ===
Enter your name: Keerthi
Enter your age: 21
Enter your email: keerthi@example.com
Enter your phone number: 9876543210
```

Enter your city: Vijayapura
Enter your course: Electronics and Communication Engineering

--- Personal Profile ---

Name : Keerthi
Age : 21
Email : keerthi@example.com
Phone : 9876543210
City : Vijayapura
Course : Electronics and Communication Engineering

9. Interview Questions and Answers

Q: What is a variable in Python?

A: A variable is a name used to store or refer to a value.

Q: What is the difference between input() and print()?

A: input() receives data from the user, while print() displays data on the screen.

Q: What is an f-string?

A: An f-string is a formatted string that allows variables or expressions to be inserted directly inside a string using curly braces.

Q: Why is type conversion required for user input?

A: input() returns the entered value as a string. Type conversion changes it to a suitable data type, such as int, when a numerical value is needed.

10. Submission Checklist

Item	Status
Python source file	Included
Sample program output	Included
README.md	Included
Project report PDF	Included
Public GitHub repository	To be created by student
GitHub link submitted through internship portal	To be completed by student
LinkedIn sharing	Required by the provided internship notice; to be completed

Note: The provided internship notice mentions deployment configuration and rollback evidence as general submission requirements. This particular task is a standalone console-based Python program and does not require deployment or rollback. If the portal explicitly requires those artifacts for every task, follow the portal's latest instructions.
